Action semantics-directed prototyping ☆

Kyung-Goo Doh [1], David A Schmidt [2]

Abstract

We present a methodology for compiler synthesis based on Mosses-Watt's action semantics. Each action in action semantics notation is assigned specific "analysis functions", such as a typing function and a binding-time function. When a language is given an action semantics, the typing and binding-time functions for the individual actions compose into typing and binding-time analyses for the language; these are implemented as the type checker and static semantics processor, respectively, in the synthesized compiler. Other analyses can be similarly formalized and implemented. We show a sample language semantics and its synthesized compiler, and we describe the compiler synthesizer that we have developed.

Now Every Company Is A Software Company

Everybody in this country should learn to ~~program~~ **use** a computer, ~~because it teaches you how to think~~ **period!**

- Steve Jobs -

Defining Injection Attacks

Donald Ray and Jay Ligatti

Abstract Parsing + Security Analysis

The Secure Injection Principle

Suppose that an application program is written to dynamically generate an output in language L. Then the secure injection principle for defensive programming is suggested as follows:

(1) When an input is injected to become all or part of a string literal in the output, any character can be injected *verbatim* except some special-purpose characters that should be sanitized as follows:
- the character ' is escaped to be \' if it is used as a string delimiter,
- the character " is escaped to be \" if it is used as a string delimiter, and
- the character \ is escaped to be \\ if it becomes the final character of an assembled string literal.

(2) When injected elsewhere, an input should be a *syntactically legal and fully evaluated term* in L and only injected to be an *expression*.

Abstract Parsing + Security Analysis

The Secure Injection Principle

Suppose that an application program is written to dynamically generate an output in language L. Then the secure injection principle for defensive programming is suggested as follows:

(1) When an input is injected to become all or part of a string literal in the output, any character can be injected *verbatim* except some special-purpose characters that should be sanitized as follows:
   - the character `'` is escaped to be `\'` if it is used as a string delimiter,
   - the character `"` is escaped to be `\"` if it is used as a string delimiter, and
   - the character `\` is escaped to be `\\` if it becomes the final character of an assembled string literal.

(2) When injected elsewhere, an input should be a *syntactically legal and fully evaluated term* in L and only injected to be an *expression*.

Theorem

Injection attacks defined in Ray and Ligatti's papers [1, 2] are all incapacitated when the output-assembling program is written fully in compliance with the secure injection principle.
